WORK ON BLOOD SUBSTITUTES IN THE USSR[Collated Report]

Emphasis in the USSR has not been placed so much on the production of synthetic substitutes for blood or blood plasma as on the perfection of techniques for the preservation of blood or blood components and their use in transfusions. According to comments made in connection with the XXVIII th plenary meeting of the Central Order of Lenin Institute of Hematology and Blood Transfusion held in the Spring of 1950, the Russians consider their scientists to be far ahead of foreign workers in this field, and believe that the most perfect organization in the world for supplying hospitals with blood has been created in the USSR. The account of the meeting in question refers to work on a new USSR blood stabilizer named "Hetrog", on the possibility of replacing dextrose and saccharose with other sugars, on the bactericidal properties of blood, on blood plasma protein fractions, on new methods for testing the quality of preserved blood and on perfected methods for preserving placental blood

As far as the use of substitutes for human blood is concerned, application in human medicine of specially treated serum obtained from the blood of cattle is the most striking development. In 1943, Acad N. G. Belen'kiy succeeded in freeing cattle serum from primary toxic and anaphylactic effects. The result was the so-called VNS (species non-specific serum), which was found to have a favorable action similar to that of homogenous plasma or serum when introduced into the bloodstream of animals of other species and man 

According to the results obtained by USSR investigators, VNS is superior to

both human blood plasma and artificial media as a vehicle for preserving human erythrocytes. A combination of human erythrocytes with VMS is supposed to be an excellent substitute for whole human blood whenever a transfusion is required [redacted] VMS has been used therapeutically on 1000 human patients

at the Inst. Imeni Sklifosovskiy, mainly as a substitute for human plasma. The experience acquired there led to the conclusion that VMS has a powerful hemodynamic, replacing, detoxifying, and stimulating action which is not inferior to that of human plasma [A. S. Smirnov, Reactions Resulting from the Infusion of VMS, Sovetskaya Meditsina, Vol. XIV, No. 4, 1950, pp. 26-27] [redacted] VMS has a stimulating effect on the cardiovascular system of the patient, because the animals from which it is obtained have been subjected to extensive bloodletting. Experiments show that whenever an animal loses 40-50% of its blood, this loss of blood induces accumulation of sympathotrophic substances (hormones and stimulants) in the posthemorrhagic blood [redacted]

[redacted] VMS is now being produced on an industrial scale. The use of VMS for supplying parenteral protein nutrition has received considerable attention [cf. Belen'kiy's book entitled "Parenteral Protein Nutrition of Humans and Animals, Press of the Moscow Society of Naturalists, Moscow, 1950, 220 pp. PA 177T637]. Experiments from this point of view were first carried out on animals [redacted] and the serum is now being used for parenteral feeding in human medicine [redacted]

50X1-HUM

In discussing the therapeutic use of blood and blood components in the USSR, one may mention that Russian investigators ascribe to erythrocytes the ability to participate in phagocytosis under certain conditions [S. A. Sheynis,
